Abstract—In mixed-criticality real-time systems, it is important to handle aperiodic (event-driven) tasks without affecting the timing guarantees of periodic tasks. The Dynamic Sporadic Server (DSS) is a scheduling method designed for Earliest Deadline First (EDF) systems that addresses this problem.

DSS is defined by a period T_s and a budget C_s , but unlike traditional sporadic servers, it does not restore the full budget at every period. Instead, when an aperiodic task arrives, DSS assigns it a deadline and restores only the amount of budget that was actually used. This approach allows the processor to reach full (100 percent) utilization while ensuring that all deadlines are still met. DSS improves the response time of aperiodic tasks without compromising the guarantees of periodic tasks.

Originally introduced by Spuri and Buttazzo, DSS has been widely studied for its efficiency in managing mixed task sets under EDF scheduling. This report reviews the theory behind DSS, describes its operation (including budget management), highlights its advantages over traditional methods, and discusses potential application areas.
